

E-Commerce Company Overview

A simple digital commerce and delivery platform connecting customers, products, orders, payments, and riders through an automated backend.

1. Company Overview

The company operates an e-commerce platform where customers can browse products, place orders, make payments, and receive their purchases. The platform uses an automated backend to manage orders from the moment they are received until delivery is completed.

2. Core Operations

Area	Description
Products	Products are stored with details such as name, unit price, quantity, and availability.
Customers	Customer information includes name, email, phone number, and delivery address.
Orders	Each order receives a unique order reference and contains the customer's purchase details.
Payments	The system records payment status such as pending, paid, or failed.
Delivery	Orders are assigned to available riders and tracked through delivery statuses.

3. Order and Delivery Workflow

Customer places order → Order is validated → Payment is confirmed → Available rider is assigned → Rider receives delivery information → Rider picks up package → Rider travels to customer → Order is delivered → Delivery status is updated.

4. Automated Backend

The backend can use workflow automation to reduce manual work. For example, an automation platform such as n8n can receive an order through a webhook, sanitize and validate the data, store the order in a database, find an available rider, assign the rider, and send email or messaging notifications.

5. Rider Management

Each rider has a unique rider ID, such as RIDER001. The system can maintain rider availability and assign an order to one available rider. After assignment, the rider can update the delivery status as the package moves through the delivery process.

6. Example Order

Field	Example
Order Reference	ORD-0014
Customer	Chinaecherem
Amount	■170,000
Payment Status	Paid
Delivery Status	Assigned
Rider	RIDER001
Delivery Address	Benin City, Edo State

7. Customer Communication

Automated notifications can keep customers informed when an order is confirmed, assigned to a rider, picked up, placed on the way, or delivered. Company-generated notifications should clearly identify the order and its current delivery status.

8. Technology Structure

A typical implementation can combine an e-commerce frontend, an API/backend, a database such as PostgreSQL or MongoDB, workflow automation through n8n, email or messaging services, and an AI agent where intelligent customer or operational support is required.

Goal

The overall goal is to create a reliable, automated e-commerce operation where orders are processed accurately, riders receive the right delivery information, and customers receive timely updates from purchase to delivery.
